where it is essential to elucidate the influences which mind exercises upon matter in different conditions of health and disease.

In the nervous apparatus of man we find two well-marked and distinct systems,—the cerebro-spinal, and the sympathetic or ganglionic system. The cerebro-spinal consists of the brain, the spinal cord, and the nerves, which extend these great centres to the ultimate extremities of the body.

The brain is composed of a soft, pulpy tissue, and is inclosed in the cavity formed by the cranium. The mass of the brain is divided into two principal portions, called the cerebrum, or front brain, and the cerebellum, or back brain.

The cerebrum occupies all the anterior and upper part of the cranial cavity; it also extends to the posterior region of the head, covering the upper portion of the cerebellum, and resting on the membranes which divide the two. It is seven-eighths larger than the cerebellum, and is supposed to be the principal seat of the intellectual faculties.

The mass of the cerebrum is divided into two hemispheres or lateral halves, and again, these have three prominences on either side, called lobes. The lobes are the special masses which fill the concave portion of the skull at the forehead, temples, and back of the head.

The hemispheres are divided by a double fold of membrane, which dips down between them, and cuts the cerebrum into two distinct halves. There are transverse bands of nervous matter connecting these hemispheres, called commissures, and the last and
