largest of these is situated at the base of the cerebrum, forming a strong band of nerve-fibres, called the corpus-callosum. Toward the base of the cerebrum it becomes inflected inward, then expands, and forms an intricate cavity, with several chambers, called ventricles.

The surface of the cerebrum is folded up into an immense number of convolutions, which pierce deeply into the substance, and form a complete mass of fissures and eminences. Brain-matter, although uniform in consistence, presents two striking varieties of color, and a specialty in the arrangement of its surfaces. The external surface is composed of a thick layer of nervous matter of a gray color, called, from its ash-like hue, cineritious; and this dips down into all the convolutions, piercing the internal mass in a well-defined, though exceedingly irregular, layer.

This interior mass is of a milky-white substance, semi-fluid in consistency, and is called medullary. Notwithstanding the irregularity of surface occasioned by the convoluted nature of the cineritious layer, it does not commingle with the medullary, but the gray and white substances preserve their distinct positions throughout the whole mass. The brain is more abundantly supplied with blood than any other organ of the body; but if the extent of brain-surface were limited by the size of the mass, only one-tenth of the quantity of blood would be sent to the brain that it now receives; and the additional provision for its nutrition is derived from the blood-vessels spread out on the membranes, and piercing all the convolutions into which the mass is folded.
