The spinal cord is enlarged at the neck and loins, and from these expansions are given off the nerves which supply the upper and lower extremities.

From the spinal cord are given off thirty-two pairs of nerves, the roots of which spring from either side of the cord, right and left.

The first eight pairs arise in the region of the neck, and are called *Cervical.*

The next twelve pairs, corresponding to the number of the ribs, are termed *Dorsal.*

Then five pairs, which spring from the lumbar vertebræ.

The remaining six pairs originate in the vertebral bones, which divide the basin of the pelvis and supply the lower abdominal regions.

Every nerve-trunk arises from a distinct root, and these roots originate in pairs, one in the anterior and the other in the posterior half of the column.

The nerves which spring from the posterior half are nerves of sensation; those from the anterior division of the cord, motor nerves. Like the columns of the medulla oblongata, if one of the sensory nerves be divided at any portion of its length, the ultimate point which it supplies becomes destitute of sensation. A corresponding effect is produced by dividing a motor nerve: the muscle or joint with which it communicates will never more move, and that result follows notwithstanding that the brain and spinal cord may remain in their perfect integrity.

To cut or sever a cord itself in any portion of its length is paralysis of both motion and sensation in all those parts of the body supplied by the nerves
