under the influence of the pneumogastric and spinal accessory nerves, also from the ganglionic or sympathetic system, the nerves of which supply the functions of organic life; but whatever motions are produced under the influence of nerve-action, are telegraphed back to the brain by reflex action.

When the organism is in health, the motions that proceed in the various departments of organic life are so mechanically perfect, that they produce no other sensation than a generally exhilarating realization of life; but when, on the contrary, there is a lack of *equilibrium* in the organism, and torpidity or excessive action ensues, the result is disease, and the announcement of its presence is telegraphed to the brain in the sensation called pain.

Possibly it may be argued against this position, that the ganglionic nerves (the system which supplies the viscera, and is profusely distributed about the head and trunk) are neither sensory nor motor, hence that those portions of the organism supplied by the sympathetic system do not convey to the brain the sensations of pain.

To fully comprehend the working of this complex scheme of nervous action, we must consider the nature and origin of the ganglionic or sympathetic system, and its connection with the cerebro-spinal nerves. (See Fig. 5.)

The sympathetic system consists of a double chain of nervous ganglia, running along the front and sides of the spinal column, and connected with each other by slender longitudinal filaments. Each ganglion is reinforced by a motor and a sensitive filament, de-
