rived from the cerebro-spinal system, and thus the organs supplied by the sympathetic nerves are brought directly into communication with the brain, which is kept informed of all the influences operating on the various organs supplied by the sympathetics. The nerves of this system are distributed to the heart, liver, spleen, kidneys, intestines, generative organs, head, neck, lungs, and blood-vessels.

The whole organism abounds in ganglia, which form plexuses of glands and nerves, and completely overlay the organs which they supply. Masses of sympathetic ganglia abound in the abdominal regions, the largest of which, from its numerous inosculations, has been named the *solar plexus;* but the entire system communicates, first with each ramification of its own system, next with the cerebro-spinal system, and finally with all the internal viscera.

Notwithstanding the connections between the two systems are preserved throughout the body, they are nevertheless much scattered; and as the sensory and motor nerves do not penetrate into the internal portions of the organism, where the sympathetics most abound, it follows that the telegraphic communications which the latter send off to the brain must proceed more slowly, as they act through a secondary system. It is for this reason that the parts of the body immediately under the influence of the cerebro-spinal nerves are more sensitive to pain than those supplied by the sympathetics. The sensations travel more slowly, and the motions, being purely instinctive, do not report themselves to the brain as directly as those operating immediately under the
