of motion. Thus electricity and vital force are assimilated.

Curative and pathogenic agents of all kinds, electricity included, are such by virtue of the forces or modes of molecular motion, which they are able to excite in the living organism,—*i.e.*, in the sphere of vital force.

Curative and pathogenic agents aside from hygienic agents, and such like, differ from each other only in consequence of their force-waves; being homologous, or heterologous with objective forces. The homologous co-operate in maintaining health and in curing disease; the heterologous impair health and prevent cure.

Electricity, in its many modifications, may be so administered as to be thus homologous to the organism as a whole, as well as locally; and, on the other hand; so as to be heterologous; hence, may be both curative and pathogenic.

Graduation of quantity and tension of the electrical currents; the choice of the currents themselves; a minute subdivision or otherwise of such currents, by slow or rapid interruptions; the discriminating application of the negative and positive poles; and the direction and course of the currents, are the ordinary means of rendering the use of this agent curative in disease. And whatever be the electric-curative, it may be relied on as certain that a misuse of the same agent will result unfortunately, and with detriment to health.

The word quantity is often confounded with the word primary, as applied to currents; and the word
