also a condition; the—large or small amount of—electricity is concentrated; drawn, as it were, from a nebulous diffusion into the form of a thunder-bolt, and thus made intensely polar, and so capable of passing, in comparatively tenuous lines, through intervening matter, instead of over it, and only into it.

From the foregoing, we shall see why we must still use the primary current in most cases requiring the condition named quantity; and the secondary current in most cases requiring the condition called intensity; without forgetting that the primary current may be had in high tension, or that the secondary current may be had in connection with great amount, provided the coils be not destroyed in its passage.

All these variations have an individuality as well as a therapeutic value of their own. Thus the primary current, applied to tumors, is highly electrolytic,—having the power to decompose morbid matter.* It affects healthy muscles, on the other hand, very little; but the secondary affects muscles very much (the amount aside).

Muscles with eccentric paralysis, as from lead, on the contrary, are very apt to be responsive, more or less, to the primary, not at all to the secondary current. Electrical gymnastics restore such muscles and their nerves; using always the current which most affects them, and changing as their approach to health alters their susceptibility.

---

* This is especially marked in the current produced by the SILVER HELIX recently invented and patented by the author.
