the contracted side of the spinal curve or curves, and the negative pole on the outer or peripheral aspect of the curvature.

First. The patient should be stripped and placed upon a flat table or pillowless lounge, although the table is preferable for many reasons, and the operator should be assisted by a well-trained hand, so that the patient may be stretched by grasping the ankles and under the arms, and at the expiration of breath, proceed to stretch steadily together, always expending more strength on the contracted limbs. This should be done successively during each treatment not more than six or eight times; during this stretching the electricity should be applied as follows:

No. 5 from the base of brain down the spine in A, No. 8 from the coccyx up to the lumbar region in D, ten minutes.

Second. Then turn the patient face downward, a sponge-cup on the inward curve in G, sponge-cup on the outer peripheral of the curve, in D, altering the negative and positive as the curves deflect in or out; this ten minutes. The patient should be instructed in a series of gymnastics in order to call into action and encourage normal activity of the muscles and circulation.

Third. Every fourth day vapor-bath, or foot-bath, the feet should be placed in hot water with the round electrode in D, sponge-cup stroked down the spine from the base of brain to coccyx in A, and about once a week the patient should be seated on No. 7 electrode in G; the sponge-cup from base of brain down to coccyx, in D, ten minutes; then vigor-
